# 1 Elliptic Curves

## 1.1 Definition

An elliptic curve  $E$  is a set of points such that

$$E = \{(x, y) \mid y^2 = x^3 + ax + b\} \cup \{O\}, \quad 4a^3 + 27b^2 \neq 0$$

Where  $O$  is a point at infinity.

The elliptic curve is symmetrical about the x-axis.

The opposite of a point  $P$  is its reflection  $-P$ .

The coefficients  $a, b$  be part of

- $\mathbb{R}$  Real numbers
- $\mathbb{Q}$  Rational numbers
- $\mathbb{C}$  Complex numbers
- $\mathbb{Z}/p\mathbb{Z}$  Finite field

## 1.2 Addition

Given two points  $P, Q \in E$  we can describe a unique third point.

We take the line that intersects  $P$  and  $Q$ , the opposite of the third intersection with the curve is out point.

$$P + Q = -R$$

If  $P = Q$ , the intersection line will be given by the tangent at that point.

If  $P = -Q$ ,  $P + Q = O$ .

If  $P = -P$  (inflection point, the concavity of the curve changes)  $R = P$ ,  $P + P = -P = P$ .

We consider  $-O$  to be  $O$ .

The intersection line  $mx + q$  is given by

$$m = \frac{P_y - Q_y}{P_x - Q_x}$$

and

$$q = P_y - mP_x$$

### 1.3 Scalar Multiplication

Given a point  $P \in E$ , multiplying  $kP$  where  $k \in \mathbb{Z}$  is equivalent to adding  $P$  to itself  $k$  times. Computing  $2P$  is the equivalent of  $P + P$  which can be calculated as  $P + Q = -R$ .

## 2 Finite field

## 3 Diffie Hellman

### 3.1 Definition

Diffie–Hellman key exchange is a method of securely exchanging cryptographic keys over a public channel.
