## 1 De Moivre's Theorem

Using the property of exponentiation  $(a^b)^c = a^{bc}$ , we can see that  $(e^{i\theta})^n = e^{in\theta}$ . Using Euler's formula we can deduce that

$$(\cos(\theta) + i \sin(\theta))^n = \cos(n\theta) + i \sin(n\theta), \quad n \in \mathbb{Z}$$

## 2 Nth Roots of Units

We can extend De Moivre's Theorem for the integers powers or any complex number, rather than the ones on the unit circle ( $r = 1$ ).

$$(r (\cos(\theta) + i \sin(\theta)))^n = r^n (\cos(n\theta) + i \sin(n\theta)), \quad n \in \mathbb{Z}$$

The  $n$ th roots of 1 are the solutions to

$$x^n = 1$$

for a given  $n$ . We might write 1 as a complex number

$$x^n = \cos(0) + i \sin(0)$$

Comparing this to our extended De Moivre's theorem

$$\cos(0) + i \sin(0) = r^n (\cos(n\theta) + i \sin(n\theta))$$

We can see that

$$\begin{aligned} r^n &= 1 \\ n\theta &= 0 \end{aligned}$$

As long as  $n \neq 0$

$$\begin{aligned} r &= 1 \\ \theta &= 0 \end{aligned}$$

By plugging these values into

$$x^n = (r (\cos(\theta) + i \sin(\theta)))^n$$

we get that  $x = 1$ .

However we could also write 1 as

$$\cos(2k\pi) + i \sin(2k\pi), \quad k \in \mathbb{Z}$$

We would then get that

$$\begin{aligned} r^n &= 1 \\ n\theta &= 2k\pi \end{aligned}$$

When solving for  $x$  again we get

$$\begin{aligned} x^n &= (r(\cos(\theta) + i\sin(\theta)))^n \\ &= \left( \cos\left(\frac{2k\pi}{n}\right) + i\sin\left(\frac{2k\pi}{n}\right) \right)^n \end{aligned}$$

concluding that

$$x = \cos\left(\frac{2k\pi}{n}\right) + i\sin\left(\frac{2k\pi}{n}\right)$$

This gives us a solution for each  $k$ , however the solutions are redundant for  $k \geq n$ . In fact, the roots of unity of  $n$  are  $n$  distinct solutions (points on the unit circle).

The roots of unity have the same angle  $\alpha = \frac{2\pi}{n}$  between each other.  
The first root of unity counter-clockwise is denoted  $\zeta_n$  because each subsequent root is a power of  $\zeta_n$ . In this case,  $\zeta_7$ .

### 3 Riemann Spheres

A Riemann sphere is a unit sphere used to represent the complex plane using stereographic projection.

The Riemann sphere lies on the complex plane. A complex number is represented by the intersection between the sphere and a ray starting from the topmost point of the sphere and intersecting with the given complex number on the complex plane.

### 4 Subsets of the complex plane

#### 4.1 Open Disk

An open disk  $D_\delta(z_0)$  is the set of points with distance less than  $\delta$  from  $z_0$

$$D_\delta(z_0) = \{z \in \mathbb{C} \mid |z - z_0| < \delta\}$$

#### 4.2 Closed Disk

A closed open disk  $D_\delta(z_0)$  is the set of points with distance less than or equal to  $\delta$  from  $z_0$

$$\overline{D_\delta(z_0)} = \{z \in \mathbb{C} \mid |z - z_0| \leq \delta\}$$

#### 4.3 Circle

A circle  $C_\delta(z_0)$  is the set of points with distance equal to  $\delta$  from  $z_0$

$$C_\delta(z_0) = \{z \in \mathbb{C} \mid |z - z_0| = \delta\}$$

#### 4.4 Interior point

$z$  is an interior point of  $\Omega$  iff there is an open disk at  $z$  whose point are in  $\Omega$

$$\exists D_{r>0}(z) \subset \Omega$$

## 4.5 Boundary point

$z$  is a boundary point of  $\Omega$  iff every open disk at  $z$  contains points both in  $\Omega$  and not in  $\Omega$ .

## 4.6 Exterior point

$z$  is an exterior point of  $\Omega$  iff it is not a boundary point of an interior point.

## 4.7 Accumulation points

$z$  is an accumulation point or limit point of  $\Omega$  if any  $D_\delta(z) \setminus \{z\}$  always contains points of  $\Omega$ .

In order to always contain points of  $\Omega$ ,  $\Omega$  must have an infinite amount of points, since  $\delta$  can be as little as we want.

## 4.8 Open sets

A set  $\Omega$  is called open iff all points in  $\Omega$  are interior points of  $\Omega$ .

## 4.9 Closed sets

A set  $\Omega$  is closed if every accumulation point of  $\Omega$  is in  $\Omega$ .

## 4.10 Bounded Set

A set  $\Omega$  is bounded iff

$$\exists M > 0 \mid \Omega \subset D_M(0)$$

In other words there must exist an  $M > 0$  such that  $\forall z \in \Omega : |z| < M$

## 4.11 Connected Set

An open set  $\Omega$  is connected iff it cannot be written as  $\Omega = \Omega_1 \cup \Omega_2$  where  $\Omega_1 \cap \Omega_2 = \emptyset$ . In other words any two points in  $\Omega$  must be connectable by a continuous curve where all the points of the curve are also in  $\Omega$ .
