# 1 Fields of Study

## 1.1 Complexity Theory

Classify problems according to their degree of "difficulty".

## 1.2 Computability Theory

Classify problems as being solvable or unsolvable.

## 1.3 Automata Theory

Compare different computation models.

# 2 Alphabets and Languages

An *alphabet* is a finite set of *symbols*. For example:  $\{a, b, c, \dots, z\}$

The set  $\{0, 1\}$  is the binary set. The empty string is denoted  $\lambda$ .

Note that  $\lambda \neq \emptyset \neq \{\lambda\}$ .

The length of a string  $w$  is denoted as  $|w|$ .

If  $\Sigma$  is an alphabet,

$$\Sigma_\lambda = \lambda \cup \Sigma$$

A set of strings is called a *language*.

# 3 Deterministic Finite Automaton

A deterministic finite automaton (DFA) is a state-machine which processes a string symbol by symbol from left to right. The automaton is in one of his *states* after processing a symbol. The machine might terminate in an *accept state* or not.

A DFA  $M = (Q, \Sigma, \delta, q, F)$

- $Q$  is a finite set of *states*
- $\Sigma$  is an alphabet
- $\delta : Q \times \Sigma \rightarrow Q$  is the *transition function*
- $q$  is an element of  $Q$  called the *start state*
- $F$  is a subset of  $Q$  which contains the *accept states*

The transition function is the logical components, it determines in which state the machine will be after processing a symbol at any state.

The following automaton processes a binary string. The start state is  $q_1$  and the only accept state is  $q_3$ . The program moves to the next state only if the symbol is 1, so it will reach  $q_3$  only if the input string contains at least two 1s.

If a DFA is in a state  $r$  and it reads the symbol  $a$ , then it will uniquely switch to the state  $\delta(r, a)$

The language of  $M$ , denoted  $L(M)$  is the set of all accepted strings by  $M$ .

$$L(M) = \{w \in \Sigma^* \mid M \text{ accepts } w\}$$

## 4 Operations

### 4.1 Concatenation

If  $A$  and  $B$  are two languages over the same alphabet, the concatenation of  $A$  and  $B$  is defined as

$$AB = \{ab \mid a \in A \wedge b \in B\}$$

### 4.2 Kleene star operator

The kleene star operator can be applied to alphabets or languages. It represent the union of all  $n$ -permutations of the set.

The set  $\{0, 1\}^*$  is the set of all binary strings. If  $\Sigma$  is an alphabet,  $\Sigma^*$  is the set of all strings over  $\Sigma$

$$\Sigma^* = \lambda \cup \bigcup_{n \in \mathbb{N}} \Sigma^n$$

## 5 Regular language

A language is regular if an automaton that accepts said language exists.  $A$  is regular iff

$$\exists M \mid L(M) = A$$

### 5.1 Closure under union (extra)

*If  $A$  and  $B$  are two regular languages over the same alphabet  $\Sigma$ , then  $A \cup B$  is also regular.*

We can prove this by making a DFA that accepts both languages. Let's say that  $M_1 = (Q_1, \Sigma, \delta_1, q_1, F_1)$  accepts  $A$  and  $M_2 = (Q_2, \Sigma, \delta_2, q_2, F_2)$  accepts  $B$ . The automaton  $M = (Q, \Sigma, \delta, q, F)$  must run  $M_1$  and  $M_2$  *simultaneously*, so any state must represent the current states of  $M_1$  and  $M_2$ . This means that the states of  $M$  must represent any combination of state between  $M_1$  and  $M_2$ , meaning  $Q = Q_1 \times Q_2$ . The transition function is now in the form  $\delta((r_1, r_2), a) = (\delta_1(r_1, a), \delta_2(r_2, a))$  where  $a \in \Sigma$ . The initial state is the state in  $Q$  which contains the initial state of  $M_1$  and  $M_2$ , namely  $(q_1, q_2)$ . Finally, the set of accept states is every tuple in  $Q_1$  containing a state in  $F_2$  or in  $Q_2$  containing a state in  $F_1$ , namely  $Q_1 \times F_2 \cup Q_2 \times F_1$ .

We can conclude that  $M = (Q_1 \times Q_2, \Sigma, \delta((r_1, r_2), a), (q_1, q_2), Q_1 \times F_2 \cup Q_2 \times F_1)$  accepts  $A \cup B$  so  $A \cup B$  is regular.

## 6 Nondeterministic Finite Automaton

Nondeterministic finite automata (NFA) are state-machines like DFAs but can change multiple states at a time by processing empty strings  $\lambda$  and when processing a symbol  $a$  may have multiple possible states to switch to. The NFA will choose the "correct" switch in order to end in an accept state, if possible.

The following automaton where  $\Sigma = \{1\}$  will end in an accept state if the input has length which is a multiple of 2 or 3.

The first switch is done by processing an empty string and the direction is chosen magically in order to end in an accept state.

A NFA is defined as  $M = (Q, \Sigma, \delta, q, F)$  where

- $Q$  is a finite set of *states*
- $\Sigma$  is an alphabet
- $\delta : Q \times \Sigma_{\lambda} \rightarrow \mathcal{P}(Q)$  is the *transition function*
- $q$  is an element of  $Q$  called the *start state*
- $F$  is a subset of  $Q$  which contains the *accept states*

## 7 Equivalence of DFAs and NFAs

Anything that can be computed by a NFA can also be computed by a DFA and vice versa.

### 7.1 DFA to NFA conversion

Let  $M = (Q, \Sigma, \delta, q, F)$  be a DFA.  $\delta$  is not a transition function of a NFA, so we need to redefine it as  $\delta'$ . Since  $\delta$  cannot process  $\lambda$ ,  $\delta'$  is defined as

$$\delta'(r, a) = \begin{cases} \delta(r, a) & x \neq \lambda \\ \emptyset & x = \lambda \end{cases}$$

where  $r$  is a state in  $Q$  and  $a$  is a symbol in  $\Sigma_{\lambda}$ .

We can conclude that  $N = (Q, \Sigma, \delta', q, F)$ .

## 7.2 NFA to DFA conversion

Let  $N = (Q, \Sigma, \delta, q, F)$  be a NFA. The idea is to construct a DFA  $M = (Q', \Sigma, \delta', q', F')$  that runs all the possible combinations that could be run by  $N$  at the same time. Any state of  $M$  is a set of states  $R \in \mathcal{P}(Q)$ , so we will say that  $Q' = \mathcal{P}(Q)$ . The set of accept states is any state  $R$  which contains an accept state of  $N$

$$F' = \{R \in Q' \mid R \cap F \neq \emptyset\}$$

Let's assume that  $N$  does not execute any  $\lambda$ -transitions.  $q'$  would be  $\{q\}$  and  $\delta'$  would be

$$\delta'(R, a) = \bigcup_{r \in R} \delta(r, a)$$

which is the union of all possible states  $N$  could switch to. Recall that for every  $r \in R$ ,  $\delta(r, a)$  is a set of all possible states to switch to.

Let's now remove the previous assumption. Now,  $M$  must also consider every state that could be reached by making zero or more  $\lambda$ -transitions. The  $\lambda$ -closure for a state  $r$ ,  $C_\lambda(r)$ , is defined as the set of all possible states that can be reached from  $r$  by making zero or more  $\lambda$ -transitions. The  $\lambda$ -closure for a set of states  $R$  is defined as

$$C_\lambda(R) = \bigcup_{r \in R} C_\lambda(r)$$

The initial state  $q'$  is now given by  $C_\lambda(q)$  and the transition function

$$\delta'(R, a) = \bigcup_{r \in R} C_\lambda(\delta(r, a))$$

## 8 Closure under regular operations

We proved using DFAs that if  $A$  and  $B$  are two regular languages over  $\Sigma$ , then  $A \cup B$  is also regular.

$$\exists M \mid L(M) = A \cup B$$

We can prove the closure under regular operations using NFAs.

### 8.1 Closure under union

*If  $A$  and  $B$  are two regular languages over the same alphabet  $\Sigma$ , then  $A \cup B$  is also regular.*

Let  $N_1 = (Q_1, \Sigma, \delta_1, q_1, F_1)$  and  $N_2 = (Q_2, \Sigma, \delta_2, q_2, F_2)$  be two NFAs such that  $A_1 = L(N_1)$  and  $A_2 = L(N_2)$ . We can construct another NFA  $N = (Q, \Sigma, \delta, q_0, F)$  such that  $L(N) = A \cup B$ .  $N$  will either go to  $N_1$  or  $N_2$  by making a  $\lambda$ -transition.

- $Q = \{q_0\} \cup Q_1 \cup Q_2$
- $F = F_1 \cup F_2$
- 

$$\delta(r, a) = \begin{cases} \delta_1(r, a) & r \in Q_1 \\ \delta_2(r, a) & r \in Q_2 \\ \{q_1, q_2\} & r = \lambda \\ \emptyset & r \neq \lambda \end{cases}$$

## 8.2 Closure under concatenation

If  $A$  and  $B$  are two regular languages over the same alphabet  $\Sigma$ , then  $AB$  is also regular.

Let  $N_1 = (Q_1, \Sigma, \delta_1, q_1, F_1)$  and  $N_2 = (Q_2, \Sigma, \delta_2, q_2, F_2)$  be two NFAs such that  $A_1 = L(N_1)$  and  $A_2 = L(N_2)$ . We can construct another NFA  $N = (Q, \Sigma, \delta, q_0, F)$  such that  $L(N) = AB$ .  $N$  will start by executing  $N_1$ , meaning  $q_0 = q_1$ . If  $N$  switches to a state  $r \in F_1$  it can move to executing  $N_2$  with a  $\lambda$ -transition. The accepted states are only the ones of  $N_2$  meaning  $F = F_2$ .  $Q = Q_1 \cup Q_2$ . The transition function is hence defined as

$$\delta(r, a) \begin{cases} \delta_1(r, a) & (r \in Q_1 \wedge r \notin F_1) \vee (r \in F_1 \wedge r \neq \lambda) \\ \delta_1(r, a) \cup \{q_2\} & r \in F_1 \wedge r = \lambda \\ \delta_2(r, a) & r \in Q_2 \end{cases}$$

Here  $F_1 = \{q_1, q_3, q_5\}$  but the actual accept states are the ones for  $N_2$ .

## 8.3 Closure under Kleene star

If  $A$  is a regular language, then  $A^*$  is also regular.

Let  $N_1 = (Q_1, \Sigma, \delta_1, q_0, F_1)$  be a NFAs such that  $A_1 = L(N_1)$ . We can construct another NFA  $N = (Q, \Sigma, \delta, q, F)$  such that  $L(N) = A_1^*$ . We want  $N_1$  to be able to switch back to its initial point when it is in a state  $r \in F_1$ . This means that the concatenation of accepted strings can cycle one after the other. Since  $\lambda$  also needs to be accepted we need a new start state which is an accept state.

- $Q = \{q_a\} \cup Q_1$
- $q = q_a$
- $F = F_1 \cup \{q\}$

$$\delta(r, a) = \begin{cases} \delta_1(r, a) & (r \in Q_1 \wedge r \notin F_1) \vee (r \in F_1 \wedge a \neq \lambda) \\ \delta_1(r, a) \cup \{q_0\} & r \in F_1 \wedge a = \lambda \\ \{q_0\} & r = q \wedge a = \lambda \\ \emptyset & r = q \wedge a \neq \lambda \end{cases}$$

## 8.4 Closure under complement

If  $A$  is a regular language, then  $\bar{A}$  is also regular.

Let  $N_1 = (Q_1, \Sigma, \delta_1, q_0, F_1)$  be a NFAs such that  $A_1 = L(N_1)$ . We can construct another NFA  $N = (Q, \Sigma, \delta, q, F)$  such that  $L(N) = \bar{A}_1$ . Any state  $r \notin F_1$  will be able to switch to a new state  $q_a$ , which is the only accept state of  $N$ , with a  $\lambda$ -transition. This will negate any accepting state of  $N_1$  and vice versa.

- $Q = \{q_a\} \cup Q_1$
- $q = q_0$
- $F = \{q_a\}$
- 

$$\delta(r, a) = \begin{cases} \delta_1(r, a) \cup \{q_a\} & r \in F_1 \\ \delta_1(r, a) & r \notin F_1 \end{cases}$$

Here  $F_1 = \{q_0, q_2, q_4\}$ , but the only actual accept state is  $q_a$ .

## 8.5 Closure under intersection

If  $A$  and  $B$  are two regular languages over the same alphabet  $\Sigma$ , then  $A \cap B$  is also regular.

Since  $A \cup B$  is regular and  $A \cap B \subseteq A \cup B$ ,  $A \cap B$  is also regular.

## 9 Regular Expressions

A regular expression is a mean to express a language. The class of languages that can be described by regular expressions coincides with the class of regular languages.

## 10 Properties

Let  $R_1$  be a regular expression describing  $L_1$  and  $R_2$  a regular expression describing  $L_2$ .

- $\lambda$  is a regular expression describing  $\{\lambda\}$
- $\emptyset$  is a regular expression describing  $\emptyset$
- $\emptyset^*$  is a regular expression describing  $\{\lambda\}$
- Let  $\Sigma$  be a non-empty alphabet,  $\forall a \in \Sigma$ ,  $a$  is a regular expression describing  $\{a\}$
- $R_1 R_2$  is a regular expression describing  $L_1 L_2$
- $R_1 \cup R_2$  is a regular expression describing  $L_1 \cup L_2$
- $R_1 \cap R_2$  is a regular expression describing  $L_1 \cap L_2$
- $R_1^*$  is a regular expression describing  $L_1^*$
- $\bar{R}_1$  is a regular expression describing  $\bar{L}_1$

If  $L_1 = L_2$ , then we say  $R_1 = R_2$  (e.g.  $\lambda = \emptyset^*$ ).

Let  $R_1, R_2$  and  $R_3$  be regular expressions

- $R_1 \emptyset = \emptyset R_1 = \emptyset$
- $R_1 \lambda = \lambda R_1 = R_1$
- $R_1 \cup R_2 = R_2 \cup R_1$
- $R_1 \cup \emptyset = R_1$
- $R_1 \cup R_1 = R_1$
- $R_1(R_2 \cup R_3) = R_1 R_2 \cup R_1 R_3$
- $(R_1 \cup R_2)R_3 = R_1 R_3 \cup R_2 R_3$
- $R_1(R_2 R_3) = (R_1 R_2)R_3$
- $\emptyset^* = \lambda$
- $\lambda^* = \lambda$
- $(\lambda \cup R_1)^* = R_1^*$
- $(\lambda \cup R_1)(\lambda \cup R_1)^* = R_1^*$
- $R_1^*(\lambda \cup R_1) = (\lambda \cup R_1)R_1^* = R_1^*$
- $R_1^* R_2 \cup R_2 = R_1^* R_2$
- $R_1(R_2 R_1)^* = (R_1 R_2)^* R_1$
- $(R_1 \cup R_2)^* = (R_1^* R_2)^* R_1^* = (R_2^* R_1)^* R_2^*$

# 11 Equivalence of regular expressions and regular languages

## 11.1 A regular expression describes a regular language

Let  $R$  be a regular expression over  $\Sigma$ .

Assume that  $R = \lambda$ . Then  $R$  describes  $\{\lambda\}$ . This language is regular and we can prove it by constructing an NFA  $N = (Q, \Sigma, \delta, q, F)$  such that  $L(N) = \{\lambda\}$ .  $q$  is the start state,  $Q = \{q\}$ ,  $F = \{q\}$  and  $\delta(r, a) = \emptyset$  where  $a \in \Sigma_\lambda$ .

Assume that  $R = \emptyset$ . Then  $R$  describes  $\emptyset$ . This language is regular and we can prove it by constructing an NFA  $N = (Q, \Sigma, \delta, q, F)$  such that  $L(N) = \emptyset$ .  $q$  is the start state,  $Q = \{q\}$ ,  $F = \emptyset$  and  $\delta(r, a) = \emptyset$  where  $a \in \Sigma_\lambda$ .

Assume that  $R = a$  where  $a \in \Sigma$ . Then  $R$  describes  $\{a\}$ . This language is regular and we can prove it by constructing an NFA  $N = (Q, \Sigma, \delta, q, F)$  such that  $L(N) = \{a\}$ .  $q_0$  is the start state,  $Q = \{q_0, q_1\}$ ,  $F = \{q_1\}$  and

$$\delta(r, b) = \begin{cases} \{q_1\} & b = a \wedge r = q_0 \\ \emptyset & \text{otherwise} \end{cases}$$

where  $b \in \Sigma_\lambda$ .

Assume that  $R = R_1 \cup R_2$  where  $R_1$  and  $R_2$  are regular expressions. Let  $L_1$  and  $L_2$  be the languages described by  $R_1$  and  $R_2$  respectively. Assuming that  $L_1$  and  $L_2$  are regular,  $R$  then describes  $L_1 \cup L_2$  which by theorem is regular.

Assume that  $R = R_1 \cap R_2$  where  $R_1$  and  $R_2$  are regular expressions. Let  $L_1$  and  $L_2$  be the languages described by  $R_1$  and  $R_2$  respectively. Assuming that  $L_1$  and  $L_2$  are regular,  $R$  then describes  $L_1 \cap L_2$  which by theorem is regular.

Assume that  $R = R_1 R_2$  where  $R_1$  and  $R_2$  are regular expressions. Let  $L_1$  and  $L_2$  be the languages described by  $R_1$  and  $R_2$  respectively. Assuming that  $L_1$  and  $L_2$  are regular,  $R$  then describes  $L_1 L_2$  which by theorem is regular.

Assume that  $R = (R_1)^*$  where  $R_1$  is a regular expression. Let  $L_1$  be the language be described by  $R_1$ . Assuming that  $L_1$  is regular, then  $R$  describes  $(L_1)^*$  which by theorem is regular.

Assume that  $R = \bar{R}_1$  where  $R_1$  is a regular expression. Let  $L_1$  be the language be described by  $R_1$ . Assuming that  $L_1$  is regular, then  $R$  describes  $\bar{L}_1$  which by theorem is regular.

This proves that every regular expression describes a regular language since every regular expression can be broken down to regular languages.

## 11.2 A DFA can be converted into a regular expression

### 11.2.1 Solving recurrence relations

Let  $\Sigma$  be an alphabet and let  $B$ ,  $C$  and  $L$  be languages in  $\Sigma^*$  where  $\lambda \notin B$

$$L = BL \cup C \implies L = B^*C$$

In order to prove this we first show that  $B^*C \subseteq L$  by induction. Let  $w \in B^*C$ , then  $w$  is  $k \geq 0$  strings in  $B$  followed a string in  $C$ . When  $k = 0$ ,  $w \in C$  which implies  $w \in BL \cup C$  which implies  $w \in L$ . When  $k > 0$  we can write  $w$  as  $xyz$  where  $x$  is a string in  $B$ ,  $y$  is the concatenation of  $k - 1$  strings in  $B$  and  $c \in C$ . Let  $q = yz$ . Since  $q$  is a concatenation of  $k - 1$  strings of  $B$  followed by a string in  $C$ ,  $q \in L$ . Hence,  $w = xq$  where  $x \in B$  and  $q \in L$ . This shows that  $w \in BL$ . Hence,  $w \in BL \cup C$ . Since  $BL \cup C = L$ ,  $w \in L$ . This proves that  $B^*C \subseteq L$ .

Now we show that  $L \subseteq B^*C$  by induction to conclude the proof. Let  $w \in L$ . When  $|w| = 0$ ,  $w = \lambda$ . Since  $\lambda \notin B$ ,  $w \notin BL$ . This means that  $w \in C$ . Since  $C \subseteq B^*C$  the string  $w$  is also in  $B^*C$ . When  $|w| > 0$ , if  $w \in C$  then  $w \in B^*C$ . If  $w \notin C$ ,  $w \in BL$  since  $w \in L$  and  $L = BL \cup C$ . Hence,  $w = bl$  where  $b \in B$  and  $l \in L$ . Since  $\lambda \notin B$ ,  $|b| > 0$ . This means that  $|l| < |b|$  since  $|l| + |b| = |w|$ . By induction,  $l$  is a string in  $B^*C$ . Hence,  $w = bl$  where  $b \in B$  and  $l \in B^*C$ . This shows that  $w \in B(B^*C)$ . Since  $B(B^*C) \subseteq B^*C$  it follows that  $w \in B^*C$ .

### 11.2.2 The conversion

We will now prove that every DFA can be converted into a regular expression. Let  $M = (Q, \Sigma, \delta, q, F)$  be a DFA. We will prove that there exists a regular expression describing  $L(M)$ .

We define  $L_r$  where  $r \in Q$  as the set of strings  $w \in \Sigma^*$  that would be accepted by  $M$  if  $r$  were its start state, meaning the language of  $M$  if  $r$  were its start state.

## 11.3 Conclusion

Since any DFA  $M$  can be converted into a regular expression that describes  $L(M)$  and every regular expression describes a regular language, we can conclude that a language  $L$  is regular iff there exists a regular expression that describes  $L$ .
